EXISTENCE OF A UNIQUE POSITIVE CONTINUOUS SOLUTION OF AN URYSOHN QUADRATIC INTEGRAL EQUATION

M. SH. MOHAMED AND I. F. M. BEN-SAUD

ABSTRACT. In this work, we concerned with the nonlinear Urysohn quadratic integral equation
\[ x(t) = a(t) + \int_0^t f_1(t, s, x(s))ds \int_0^t f_2(t, s, x(s))ds, \quad t \in [0, T]. \]
The existence of a unique positive continuous solution will be proved. The fractional orders quadratic integral equation will be considered as an application.

1. INTRODUCTION

Quadratic integral equations (QIES) are often applicable in the theory of radiative transfer, kinetic theory of gases, in the theory of neutron transport and in the traffic theory. The quadratic integral equations can be very often encountered in many applications (see [1]-[15]). Here we are concerned with the nonlinear Urysohn quadratic integral equation
\[ x(t) = a(t) + \int_0^t f_1(t, s, x(s))ds \int_0^t f_2(t, s, x(s))ds, \quad t \in [0, T]. \] (1)
The existence of a unique positive continuous solution of will be proved.

2. MAIN RESULTS

Consider the quadratic integral equation (1) under the following assumptions
(i) \( a : I = [0, T] \to R^+ \) is continuous, \( a = \sup_{t \in [0, T]} |a(t)| \).
(ii) \( f_i : [0, T] \times [0, T] \times R \to R^+ \) are measurable in \( s \in [0, T] \) for all \( (t, x) \in [0, T] \times R \), nonincreasing in \( t \in [0, T] \) for all \( (s, x) \in [0, T] \times R \) and satisfy the Lipschitz condition
\[ |f_i(t, s, x(s)) - f_i(t, s, y(s))| \leq |k_i(t, s)| |x(s) - y(s)|, \quad i = 1, 2 \] (2)
for every \( (t, s, x(s)) \in [0, T] \times [0, T] \times R^+ \) and
\[ \int_0^t |k_i(t, s)| ds \leq K_i, \quad i = 1, 2, \quad \forall t \in [0, T]. \]
Remark From assumptions (ii) and (iii) we can get

\[ f_i(t, s, x(s)) \leq k_i(t, s)|x(t)| + f_i(t, s, 0). \]

Define the set

\[ Q_r = \{ x \in R : |x(t)| \leq r \} \subset C[0, T]. \]

The following lemma can be easily proved.

Lemma 1. Let \( x \in Q_r \). Then we have

\[ \int_0^t |f_i(t, s, x(s))| \leq K_i \ r + m_i = M_i \]

Definition By a solution of the quadratic integral equation (1) we mean a function \( x \in Q_r \). This function satisfies equation (1).

Now for the existence of a unique positive continuous solution of the quadratic integral equation (1) we have the following theorem.

Theorem 1. Let the assumptions (i)-(iii) be satisfied. If \( (M_1 K_2 + M_2 K_1) = K < 1 \), then the quadratic integral equation (1) has a unique positive solution \( x \in C[0, T] \).

Proof. Define the operator \( F \) associated with the quadratic integral equation (1), by

\[ Fx(t) = a(t) + \int_0^t f_1(t, s, x(s))ds \cdot \int_0^t f_2(t, s, x(s))ds. \]
The operator $F_2$ maps $C[0,T]$ into itself for this, if we let $x \in C[0,T]$, $t_1, t_2 \in [0,T]$, $t_1 < t_2$, and $t_2 - t_1 \leq \delta$, then

$$|Fx(t_2) - Fx(t_1)| = |a(t_2) - a(t_1)| + \int_0^{t_2} f_1(t_2, s, x(s))ds \int_0^{t_2} f_2(t_2, s, x(s))ds$$

$$- \int_0^{t_1} f_1(t_1, s, x(s))ds \int_0^{t_1} f_2(t_1, s, x(s))ds|$$

$$= |a(t_2) - a(t_1)| + \int_0^{t_1} f_1(t_1, s, x(s))ds \int_0^{t_1} f_2(t_1, s, x(s))ds$$

$$+ \int_0^{t_2} f_1(t_2, s, x(s))ds \int_0^{t_2} f_2(t_2, s, x(s))ds$$

$$- \int_0^{t_2} f_1(t_2, s, x(s))ds \int_0^{t_2} f_2(t_2, s, x(s))ds|$$

$$\leq |a(t_2) - a(t_1)| + \int_0^{t_1} f_1(t_1, s, x(s))ds \int_0^{t_1} f_2(t_1, s, x(s))ds$$

$$+ \int_0^{t_2} f_1(t_2, s, x(s))ds \int_0^{t_2} f_2(t_2, s, x(s))ds$$

$$- \int_0^{t_2} f_2(t_2, s, x(s))ds|$$

$$+ \int_0^{t_1} f_2(t_1, s, x(s))ds \int_0^{t_1} f_2(t_1, s, x(s))ds|$$

$$+ \int_0^{t_2} f_1(t_1, s, x(s))ds \int_0^{t_2} f_2(t_1, s, x(s))ds$$

$$\leq |a(t_2) - a(t_1)| + \int_0^{t_1} f_1(t_1, s, x(s))ds \int_0^{t_1} f_2(t_1, s, x(s))ds$$

$$+ \int_0^{t_2} f_1(t_2, s, x(s))ds \int_0^{t_2} f_2(t_1, s, x(s))ds$$

$$+ \int_0^{t_2} f_2(t_1, s, x(s))ds \int_0^{t_2} f_1(t_2, s, x(s))ds,$$
then
\[ |F(x_2) - F(x_1)| \leq |a(t_2) - a(t_1)| + (K_1 ||x(t)|| + M_1) \int_{t_1}^{t_2} f_2(t_1, s, x(s)) ds + (K_2 ||x(t)|| + M_2) \int_{t_1}^{t_2} f_1(t_1, s, x(s)) ds. \]

This proves that \( F_2 : C[0, T] \to C[0, T]. \)

Now to prove that \( F_2 \) is contraction, we have the following.

Let \( x, y \in C[0, T] \), then
\[
|F_x(t) - F_y(t)| = | \int_0^t f_1(t, s, x(s)) ds \int_0^t f_2(t, s, x(s)) ds - \int_0^t f_1(t, s, y(s)) ds \int_0^t f_2(t, s, y(s)) ds |
\]
\[
= | \int_0^t f_1(t, s, x(s)) ds \int_0^t f_2(t, s, x(s)) ds - \int_0^t f_1(t, s, y(s)) ds \int_0^t f_2(t, s, y(s)) ds |
\]
\[
+ | \int_0^t f_1(t, s, x(s)) ds \int_0^t f_2(t, s, y(s)) ds - \int_0^t f_1(t, s, y(s)) ds \int_0^t f_2(t, s, y(s)) ds |
\]
\[
= | \int_0^t f_1(t, s, x(s)) ds \int_0^t [f_2(t, s, x(s)) - f_2(t, s, y(s))] ds |
\]
\[
+ | \int_0^t f_2(t, s, y(s)) ds \int_0^t [f_1(t, s, x(s)) - f_1(t, s, y(s))] ds |
\]
\[
\leq | \int_0^t f_1(t, s, x(s)) ds \int_0^t |f_2(t, s, x(s)) - f_2(t, s, y(s))| ds |
\]
\[
+ | \int_0^t f_2(t, s, y(s)) ds \int_0^t |f_1(t, s, x(s)) - f_1(t, s, y(s))| ds |
\]
\[
\leq M_1 \int_0^t |k_2(t, s)| \ |x(s) - y(s)| ds + M_2 \int_0^t |k_1(t, s)| \ |x(s) - y(s)| ds.
\]

Then
\[
||F x - F y|| \leq M_1 K_2 ||x - y|| + M_2 K_1 ||x - y||
\]
\[
||F x - F y|| \leq (M_1 K_2 + M_2 K_1) ||x - y||.
\]

Hence
\[
||F x - F y|| \leq K ||x - y||.
\]

Since \( K < 1 \), then \( F_2 \) is contraction. Then by using Banach fixed point theorem, the operator \( F \) has a unique fixed point \( x \in C[0, T] \) by second group of the assumptions. ■
